1. INTRODUCTION

DTS Inc. has contracted LS telcom Inc. to conduct a study with the objective to assess the HD Radio signal maximum coordination level that existing Canadian FM stations can potentially use.

The coordination level values provided in this report are the results of an automated calculation of all operating FM stations in Canada.

In line with LS telcom's required deliverables, no in-depth engineering analysis was conducted in the course of the execution of this task assignment. Such an in-depth engineering analysis would be required for searches for distinct frequencies for establishing individual HD Radio stations in Canada or for creating a frequency plan for a nationwide introduction of HD Radio Services in the country.

We would like to mention at this point that the Department of Innovation, Science and Economic Development (ISED) of Canada, offers the possibility to apply for an experimental HD Radio Station license. In case, DTS wants to apply for such an experimental HD Radio Station license, a detailed engineering analysis would have to be carried out to establish and calculate the exact parameters of the proposed maximum coordination level for the particular station, as required by ISED Canada and the applicable related licence application documents and regulations.

This document describes the methodology as well as the output presentation format of the results of this study.

2. METHODOLOGY

2.1 SOURCE DOCUMENTS AND ASSUMPTIONS

The publicly available FM radio station database used for this study was downloaded from the ISED Canada web site (https://sms-sgs.ic.gc.ca/eic/site/sms-sgs-prod.nsf/eng/h_00015.html) on February 1st, 2017. Consequently, all data in this report are based on the information available in that specific database downloaded on that date.

Additionally, LS telcom's broadcast network planning and coordination tool suite, CHIRplus_BC version 7.0.0.7 (built IC 16.11.2016) with its advanced interference calculation functionality, was used to determine the list of stations that can potentially be affected by interference from the host (i.e. the station under study that could create interference to incumbents, from the addition of HD Radio digital carriers). The implementation of the FCC F contours in CHIRplus_BC have been utilised for all required coordination calculations.

2.2 DETAILED METHODOLOGY

From the ISED Canada database download, the Consultant extracted all regular power (as defined in ISED BPR-3[1]) FM stations (1645 stations) in Canada (marked as "OP").

Then, for each of the 1645 regular stations under study, the following steps were undertaken for conducting the analysis:

- A macro command searched through the information database for all FM stations, within a 200 km radius, that were upper and lower first adjacent to the station under test.
- All incumbent FM stations listed in the database were included in the study; stations such as: regular stations, low power, translator, allotments, temporary operations, etc.
- Then, the macro drew the F(50,50) 54 dBµV/m contour for each 1st adjacent station previously identified (lower adjacent in blue and upper in green).

[1] Department of Science, Industry and Economic Development of Canada, *Broadcasting Rules and Procedures, Part-3*, http://www.ic.gc.ca/eic/site/smt-gst.nsf/eng/sf01153.html (last consulted on April 18th, 2017)

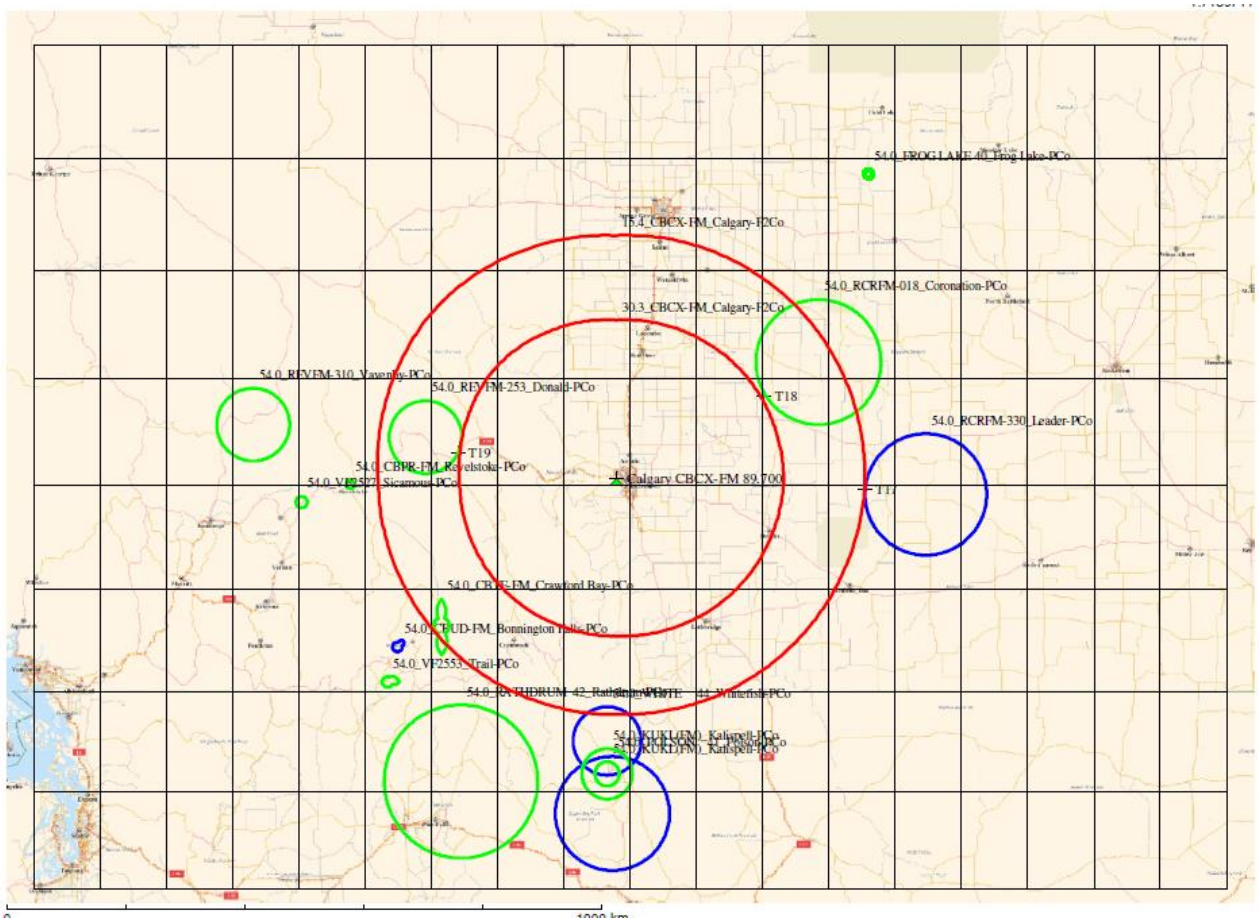

Figure 1: Example of result contour map

- The Consultant then identified the points where the limitations would occur between the station under test and the incumbent stations, with the CHIRplus_BC Test Point evaluation tool. This evaluation also included the analysis of the antenna pattern and terrain obstacles. The evaluation was done to identify the closest limitation (i.e. the point where the interfering contour of the HD Radio will intersect the protected contour of the incumbent stations) for both lower and upper adjacent channels.

- Once the limitation values were identified, the Consultant drew the maximum coordination contours F(50,10) for both lower and upper adjacent channel. The identified values were saved in MS Excel spreadsheet output format available in the MS Excel file enclosed to this report (DVD) and listed in Appendix A of this document.

- Finally, the resulting map was rescaled for clarity and saved as a PDF. The files are available on the DVD enclosed to this Report.

2.3 LIMITATIONS OF THE METHODOLOGY

We have identified the following limitations to the methodology utilised:

- Since the test points were positioned manually, it was difficult to identify the exact maximum intercept point of the 2 contours and, therefore iteration was often used. Additionally, since some contours are based on 8 radials and others on 36, there were discrepancies between the exact placement of the test point and the interpolation between 2 radials. Consequently, we consider that this methodology has an accuracy of approximately ±0.5 dB.

- All incumbent stations have been coordinated at their operating parameters (not at their Maximum Class protection parameters) levels. In Canada, this is the accepted coordination methodology but coordination with USA stations generally require protection at their Maximum Class parameters, over USA territory. Since we did not evaluate the Maximum Class protection, nor the tolerance for interference over Canadian territory for USA stations, our methodology could have yielded some gains or losses from the real cross-border coordination between Canadian and USA stations.

- Finally, there was no consideration or evaluation of potential allowable interference over large bodies of water. This would generally result in a greater potential for coordination requirement than what was calculated in this study. Upon receipt of a request from DTS, LS telcom would be pleased to offer a more in-depth engineering analysis for assessing the coordination requirements.

2.4 RESULTS INTERPRETATION

The calculated results can be categorized in 3 types:

- None: meaning that no adjacent stations within 200 km would be affected.

- 999: meaning that a first adjacent station protection contour already includes the station under test and no protection level could be achieved.

- Value in dB: representing the maximum power in dBµV/m for the F(50,10) contour of the station under test until it reaches the protected contours of the nearest incumbent station.

Two interfering contours (in red) are drawn on each map, representing the maximum point for the lower and upper adjacent channel.

© LS telcom Limited 2017

Each contour map has been saved as per the following convention:

- Saved in different folders representing each province and territory.
- The file name is based on the city and the call sign.

APPENDIX A – RESULTS

Province	City	Call sign	Freq.	Lower Limit (dBuV/m)	Upper Limit (dBuV/m)
